

Tenzin MaintenanceIQ

Pilot Collateral Packet

Discovery questions, demo flow, and pilot success criteria for practical customer conversations.

Pilot success criteria are validation goals, not guaranteed outcomes. Tenzin supports maintenance teams without replacing technicians, engineers, OEM manuals, CMMS/EAM systems, or safety procedures.

Pilot Discovery Questions

Use these questions to shape a practical Tenzin MaintenanceIQ pilot. The goal is to understand where maintenance knowledge lives today, which assets matter most, and what a useful pilot should validate.

Facility Context

- What type of facility, process, or production environment would be included in the pilot?
- Which area, line, cell, or work center would be the best starting point?
- Who would sponsor the pilot from operations, maintenance, reliability, or engineering?

Critical Assets

- Which assets cause the most downtime, troubleshooting effort, or documentation searches?
- Which assets have enough manuals, drawings, procedures, or prior notes to support a meaningful pilot?
- Are there safety-critical assets or procedures that should be excluded from early pilot scope?

Existing Documentation

- Where do manuals, OEM documents, drawings, troubleshooting guides, and procedures live today?
- Which documents are approved for technicians to use during troubleshooting?
- Are documents organized by asset, facility, line, vendor, or shared-drive folder structure?
- Are there duplicate, outdated, or incomplete documents that should be cleaned up before upload?

Information-Finding Pain Points

- What information is hardest to find during downtime or urgent troubleshooting?
- Which fault codes, alarms, symptoms, or procedures are searched for repeatedly?
- How much time do technicians typically spend looking through PDFs, binders, folders, or messages?

Maintenance Workflow

- Who usually investigates equipment issues first: operators, technicians, reliability, controls, or engineering?
- How are troubleshooting notes, fixes, and follow-up actions captured today?
- Where does handoff happen between shifts, roles, or departments?

CMMS / EAM Usage

- Which CMMS, EAM, work-order, or asset-management tools are already used?
- What information should stay in those systems rather than Tenzin MaintenanceIQ?
- Would the pilot need manual reference to existing work orders, asset names, or issue categories?

Security And Data Concerns

- What document types are acceptable for a pilot, and what should be excluded?

- Are there concerns about vendor manuals, proprietary procedures, plant layouts, or controlled documents?
- Who should have access to pilot assets, documents, answers, citations, and issue context?
- What review or approval steps are needed before uploading documents?

Pilot Scope And Success Metrics

- Which 3-10 assets would make a focused first pilot useful?
- Which document set should be uploaded first?
- What questions should the team expect Tenzin MaintenanceIQ to answer with cited sources?
- What would make the pilot worth expanding: faster document lookup, better citation traceability, technician usability, or improved issue capture?

Demo Script

This script is a lightweight guide for a customer-facing Tenzin MaintenanceIQ walkthrough. Adapt the asset names, documents, and questions to the prospect's environment when possible.

1. Frame The Problem

Start with the common maintenance challenge: equipment knowledge is scattered across manuals, PDFs, shared drives, binders, notes, and technician experience. During downtime, teams need fast answers, but they also need to know where those answers came from.

Position Tenzin MaintenanceIQ as a knowledge assistant that helps teams find and use their own documentation faster. It does not replace technicians, engineers, OEM manuals, safety procedures, or existing CMMS/EAM systems.

2. Upload And Organize Documentation

Show how approved manuals, procedures, or reference documents can be organized around facilities and assets. Keep the explanation simple: documents are connected to the equipment they support so future questions can stay asset-specific.

Suggested talk track:

- Start with a small set of approved documents.
- Link documents to the relevant asset.
- Keep source documents traceable so users can review the original page later.

3. Ask A Plain-Language Maintenance Question

Ask a realistic question a technician might ask during troubleshooting, such as a symptom, alarm, reset procedure, inspection step, or component question.

Suggested talk track:

- Users should not need to remember exact document titles or page numbers.
- The question should stay tied to the selected asset or facility context.
- If reliable source material is not available, the system should say it does not have enough information.

4. Review The Cited Answer

Walk through the answer as a starting point for investigation, not as guaranteed maintenance instruction. Point out the cited sources and explain that citations are what make the response auditable.

Suggested talk track:

- The answer is grounded in retrieved source material.
- Citations help users check the underlying manual or procedure.
- Human judgment, safety procedures, and approved documentation remain the source of truth.

5. Open The Cited Manual Page

Open a cited source from the answer. Emphasize that the user can inspect the original document page behind the response rather than trusting a summary alone.

Suggested talk track:

- This reduces time spent hunting through PDFs and folders.
- It helps technicians confirm the answer against the original source.
- It supports review by maintenance managers, reliability, or engineering.

6. Capture Feedback Or Issue Context

Show how a user can mark whether a reference was helpful or capture issue context for future troubleshooting. Keep this focused on learning from real work without turning the pilot into a full CMMS replacement.

Suggested talk track:

- Feedback helps identify which references are useful.
- Issue context can preserve what happened and what evidence supported the next step.
- Work orders and formal maintenance records can remain in the existing CMMS/EAM.

7. Explain Account And Facility Data Boundaries

Close by explaining that pilot data is organized by account, facility, asset, document, and issue context. Normal users should only work with information they are authorized to see, and source documents should be opened through authenticated application paths rather than public file links.

Suggested Close

Ask which assets, documents, and troubleshooting scenarios would make the most useful pilot. Confirm that success should be measured as validation goals, such as citation usefulness, technician usability, document lookup time, and comfort with data boundaries.

Pilot Success Criteria

Use these criteria as goals to validate during a focused Tenzin MaintenanceIQ pilot. They are not guaranteed outcomes; the pilot should confirm whether the product is useful for the selected facility, assets, documents, and workflows.

Area	What To Validate	Example Evidence
Retrieval accuracy	Questions return relevant source material for the selected asset or facility context.	Sample troubleshooting questions produce source-backed answers from the expected manuals or procedures.
Citation usefulness	Citations help users confirm the answer against the original document.	Technicians or managers can open cited manual pages and judge whether the references are useful.
Time saved finding documentation	The pilot reduces time spent searching PDFs, binders, shared drives, or messages.	Before/after lookup notes, timed demo tasks, or user feedback from common troubleshooting scenarios.
Technician usability	Technicians can ask plain-language questions and understand the response format.	Pilot users can complete common questions without heavy coaching after initial orientation.
Asset/document coverage	The selected assets have enough approved documentation to support meaningful retrieval.	A defined starter set of assets has manuals, procedures, drawings, or troubleshooting references uploaded and linked.
Feedback loop	Users can flag helpful or unhelpful answers and references.	Feedback is captured during pilot reviews and used to identify gaps in documents or answer quality.
Security/data comfort	Stakeholders are comfortable with the pilot data boundary and document handling approach.	Approved document scope, user access, and account/facility boundaries are reviewed before expansion.
Go/no-go expansion decision	The team can make a clear decision about whether to broaden scope.	Stakeholders agree to expand, revise scope, pause, or stop based on documented pilot findings.

Suggested Pilot Review Questions

- Which questions produced useful, source-backed answers?
- Which citations were helpful, missing, or confusing?
- Which documents or assets need cleanup before broader use?
- Did technicians trust the workflow enough to use it during real troubleshooting?
- What data, access, or review requirements must be addressed before expansion?
